

## Description of Power Supply PS-7251

The line voltage of 220 V is via a fuse applied to a transformer which transforms the voltage down.

There are two separated secondary coils, which after rectifying and filtering deliver voltages of 50 V and 13,5 V. The voltage of 13,5 V is stabilized and can be adjusted to a fixed value by R7. The maximum current is determined by the value of R1.

The voltage drop in R1 and Q1 is regulated by the stabilized voltage after Q1 supplying a current through R5 and the zenerdiode D4, so that the zenervoltage and with it the emitter-voltage is maintained at 6,2 V. At this the base-voltage at Q4 is about 6,9 V, maintained by the voltage-divider (R6-R7-R8). If the voltage at the output increases, the base-voltage at Q4 increases, this results in the fact that the collector-current increases, with that the base-emitter-voltage at Q3 increases and causes an increasing emitter-current through this transistor. The base-current to Q2 decreases and with it the base-current to Q1 decreases and the output-voltage decreases to the stabilized voltage-value.

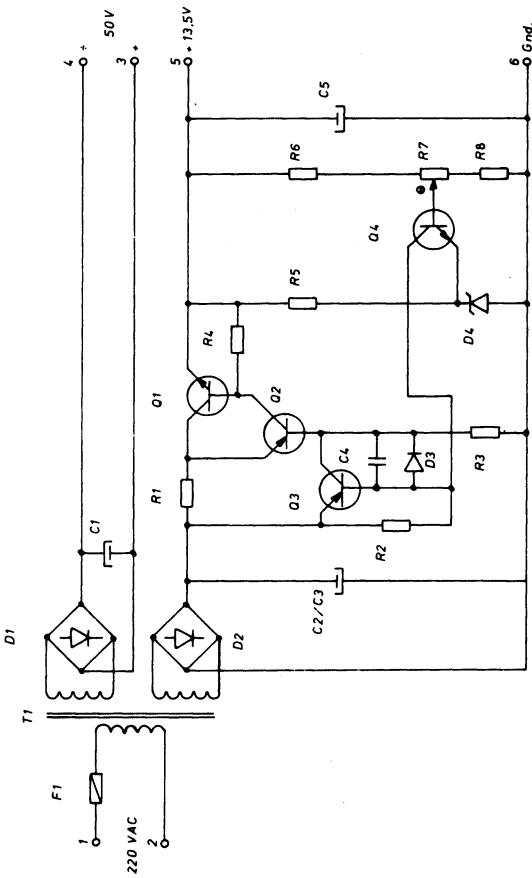

The current-limitation works like this:

If the maximum current is exceeded, the circuit shifts the function to a current-generator. Diode D3, which normally is reverse biased, begins to conduct if the voltage across R1 and the base-emitter-voltage of Q1 exceeds 1,2 V. Since  $V_{BE}$  of Q1 is constant = 0,6 V, it is seen that the limited current  $I_{max} =$

$$\frac{0,6}{R_1} .$$
